### ABSTRACT

Cs<sub>x</sub>WO<sub>3</sub> nanoparticles were successfully synthesised via solvothermal and its nanocomposites with polypyrrole and different thicknesses were prepared via interfacial polymerisation. The UV-Visible and near-infrared (UV-Vis-NIR) of Cs<sub>x</sub>WO<sub>3</sub> products were studied. The Cs<sub>x</sub>WO<sub>3</sub> and its nanocomposites characterised by X-ray diffraction (XRD), scanning electron microscopy (SEM), energy dispersive X-ray spectrometer (EDX) and FTIR. The results indicated that the NIR absorption property of Cs<sub>0.3</sub>WO<sub>2.7</sub> is better than CsWO<sub>3</sub> and increased by increasing thicknesses.

### Introduction

Hexagonal tungstate oxide nanoparticle (NPs) has received much attention because of its tunnel structure [1]. Guest ions such as Na<sup>+</sup>, NH<sub>4</sub><sup>+</sup> reside in the hexagonal window tunnels between layers and can be exchanged by K<sup>+</sup>, Cs<sup>+</sup> and others [2]. Alkali-doped tungsten bronze, M<sub>x</sub>WO<sub>3</sub> is composed of the arrays of octahedral unit WO<sub>6</sub> interconnected with their corners as is the case with tungsten trioxide ionic and electronic conductivities, which property has prompted studies seeking possible applications to sensors and superconductivity in Na<sub>x</sub>WO<sub>3</sub> [3] and Cs<sub>x</sub>WO<sub>3</sub> [4]. The effects of processing parameters such as solvent, autoclave rotating and Cs source on the morphology and microstructure of Cs<sub>x</sub>WO<sub>3</sub> products were investigated by Liu and co-workers [5]. The results showed that autoclave rotating during the reaction and using ethanol as a solvent are helpful for decreasing the particle size and obtaining pure hexagonal Cs<sub>x</sub>WO<sub>3</sub> crystals. The tungsten bronzes (M<sub>x</sub>WO<sub>3</sub>) with different ions were synthesised and their electrochromic, near-infrared (NIR), nanostructure electrical-optical properties and photothermal ablation cancer trapped were studied, too [6–9]. Recently NIR shielding materials such as BaTiO<sub>3</sub> and Cs<sub>x</sub>WO<sub>3</sub> have received considerable attention in the development of thermal IR shielding transparent and solar heat shielding for control window of automobiles and architectures [10,11]. The strong absorption in the NIR region, owing to the free electrons was obtained. They also might be efficient as a photosensitiser in NIR photothermal therapy [12]. There has been a strong desire to shield on the window of automobiles, and building [13] in order to reduce the energy consumption. For application as a heat ray shielding materials, excellent shielding ability of NIR rays as well as high visible light transparency is required. The interfacial preparation of polypyrrole (PPy) is a new and powerful method for synthesis of the soluble PPy. This advantage is due to the ease of preparation, nanorod products and its fast reaction [14]. The preceding researches, we reported some of new a nanocomposites based conducting polymers [15–18]. We have synthesised new compounds showed that suitable nanocomposites as multi absorption in

both TIR and MW [10,19]. In this work, caesium tungsten bronzes were successfully synthesised by solvothermal conditions. The Cs<sub>x</sub>WO<sub>3</sub>/PPy nanocomposites are prepared by interfacial polymerisation, too. The research results were studied for both UV-Vis (200–800 nm) and NIR (780–2400 nm) absorptions.

### Experimental

#### Materials

Tungsten hexachloride (WCl<sub>6</sub>) and caesium hydroxide (CsOH.5H<sub>2</sub>O) and benzyl alcohol solution and purchased form Merck. Pyrrole monomer (analytical grade, Merck) distilled twice under reduced pressure and stored blew 0 ° C. All the other chemical reagents were purchased from Merck without further purification.

#### Preparation of CsWO<sub>3</sub>

Caesium tungsten bronzes, Cs<sub>x</sub>WO<sub>3</sub> were successfully prepared by solvothermal reaction method. Using tungsten hexachloride (WCl<sub>6</sub>) and caesium hydroxide (CsOH.5H<sub>2</sub>O) as raw materials and benzyl alcohol solution as a reaction solvent. The initial concentration of WCl<sub>6</sub> 0.7 g (0.0017 mol) in the 30 mL (0.289 mol) benzyl alcohol solution was adjusted and the nominal atomic ratio of Cs/W was designed. The solvothermal reaction was conducted at 200 °C in 14 h for CsWO<sub>3</sub> and 240 °C in 18 h for Cs<sub>0.3</sub>WO<sub>3</sub> in an electric oven, with the reaction solution in a Teflon-lined autoclave 150 mL of internal volume. The obtained solid precipitates were then centrifuged and washed with water and ethanol a few times and followed by vacuum drying at 60 °C overnight.

#### Preparation of Cs<sub>x</sub>WO<sub>3</sub>/PPy nanocomposites via interfacial polymerisation

The synthetic procedure involves interfacial polymerisation of pyrrole in a water/chloroform interface with pyrrole

Figure 1. FTIR spectrum of a)  $Cs_xWO_3$  NPs b)  $Cs_xWO_3/PPy$  nanocomposite.

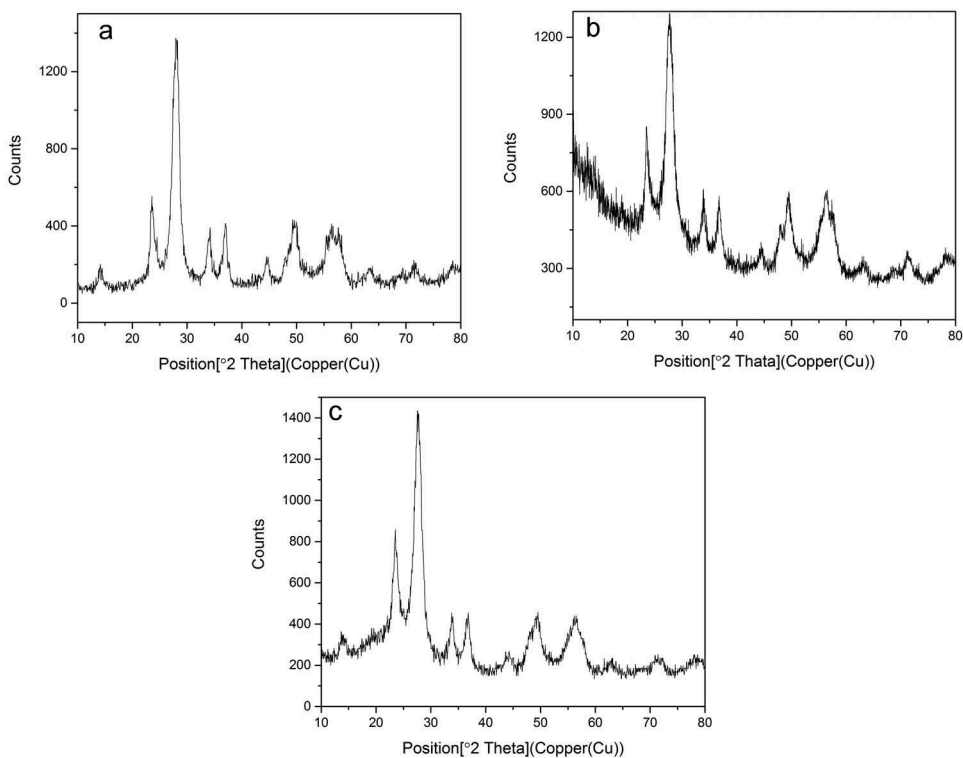

Figure 2. XRD patterns for a)  $CsWO_3$ , b)  $Cs_{0.3}WO_{2.7}$  and c)  $Cs_{0.3}WO_{2.7}/PPy$ .

monomer and  $\text{Cs}_x\text{WO}_3$  added in the organic phase, while  $\text{Fe}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$  in the aqueous phase. The aqueous solution was slowly added to the organic medium. In a typical preparation, a solution of 6 g (0.045 mol)  $\text{Fe}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$  in 35 mL of  $\text{H}_2\text{O}$  were slowly spread to 35 mL  $\text{CH}_2\text{Cl}_2$  containing 1 mL (0.015 mol) of pyrrole monomer and 0.8 g of  $\text{Cs}_x\text{WO}_3$ . As the reaction proceeded, without stirring a black film appeared in the interface. After 24 h reaction time, the  $\text{Cs}_x$

$\text{WO}_3/\text{PPy}$  nanocomposites film was removed and washed carefully by ethanol and acetone and dried at 70 °C.

### Characterisation

The ultrasonic experiment was carried out by an ultrasonic disperser (Hielsche, UP4005, Germany). Field emission scanning electron microscopy (FESEM) was performed by TESCAN

**Figure 3.** FESEM images of a)  $\text{Cs}_{0.3}\text{WO}_{2.7}$  NPs and b)  $\text{Cs}_{0.3}\text{WO}_{2.7}/\text{PPy}$  nanocomposite.

MIRA to observe surface morphologies of samples. The XRD patterns of the samples were collected on a Philips-PW 1800 with Cu  $K_{\alpha}$  radiation ( $\lambda = 1.54184 \text{ \AA}$ ) in the  $2\theta = 4\text{--}90^{\circ}$  with steps of  $0.02^{\circ}$ , scanning operated at 40 kV and 30 mA (Netherland). The UV-Vis-NIR of the samples was collected on a Analytik jena Specord 250 by ASTM E1331 standard.

## Results and discussion

### FTIR study

Figure 1(a,b) shows the FTIR spectrum of  $Cs_xWO_3$  NPs and  $Cs_xWO_3/PPy$  nanocomposite. As Figure 1(a) illustrates, the band at  $770 \text{ cm}^{-1}$  is related to special peak for  $Cs_xWO_3$  NPs. As observed in Figure 1(b), the band at  $3425 \text{ cm}^{-1}$  can be attributed to N-H stretching vibrations of PPy. In addition, the specific peaks around at  $1540$  and  $1455 \text{ cm}^{-1}$  are attributed with vibrational modes of quinonic and aromatic type ring for PPy. The peak at  $1163 \text{ cm}^{-1}$  is related to C-N stretching vibrations for PPy and we can see special peaks for  $Cs_xWO_3$  at  $600\text{--}700 \text{ cm}^{-1}$ .

### XRD patterns

Figure 2(a–c) shows XRD patterns for a)  $CsWO_3$ , b)  $Cs_{0.3}WO_{2.7}$  and c)  $Cs_xWO_3/PPy$ , respectively. Its standard correspond to JCPDS file no 98-000-4845. All peaks correspond to characteristic peaks of hexagonal type lattice. This result indicated that the increasing temperature changed  $CsWO_3$  (green colour) to  $Cs_{0.3}WO_{2.7}$  (blue colour). The average crystallite size calculated by debye sherrer formula  $\beta = k \lambda / D \cos \theta$ , where  $\lambda$  is the wavelength of Cu  $K_{\alpha}$  radiation ( $0.1541 \text{ nm}$ ) and the value of  $K$  depends on several factors, including the miller index of reflection plan and the shape of the crystal. If the shape is unknown,  $K$  is often assigned a value

of 0.89,  $D$  is average crystallite size,  $\theta$  is the Bragg's angle, and  $\beta$  is fall width at half maximum of the diffraction peaks. From the obtained peak width of XRD patterns Figure 2(a–c). So, the average crystallite sizes of  $CsWO_3$ ,  $Cs_{0.3}WO_3/PPy$  calculated as 20.71, 20.68 and 20.41 nm, respectively.

### FESEM images

Figure 3(a,b) shows FESEM images of  $Cs_{0.3}WO_{2.7}$  NPs and  $Cs_{0.3}WO_{2.7}/PPy$  nanocomposite. The diameters of NPs and nanocomposite are about 34 and 80 nm, respectively. So, PPy shell is about 45 nm. Figure 3(a) shows NP is clear and uniform and surface of SEM image of nanocomposites is spongy and uniform, too.

### EDX pattern

Figure 4 shows the typical EDX of  $Cs_xWO_3/PPy$  that  $Cs_xWO_3$  synthesised by solvothermal method for using CsCl as Cs source. The Cs/W atomic ratio of NPs based on EDX analysis is 0.3, which is close to the theoretical maximum of 0.33 [5,20]. In addition, EDX pattern proved existence of NPs in nanocomposite structure for 35% weight ratio.

### UV-Vis-NIR spectra analysis

Figure 5 shows the UV-Vis-NIR reflection spectra of  $CsWO_3$  and  $Cs_{0.3}WO_{2.7}$  plates synthesised by the solvothermal reaction, in different thicknesses. A typical UV-Vis absorption bands (200–800 nm) and NIR-absorption bands (780–2400 nm) of  $Cs_xWO_3$  NPs can be clearly seen for all samples. The former is due to the band gap and the latter is correlated with the free carrier concentration and polarons of the  $Cs_xWO_3$  products [5]. It should be noted that the reflectance peak position of  $Cs_{0.3}$

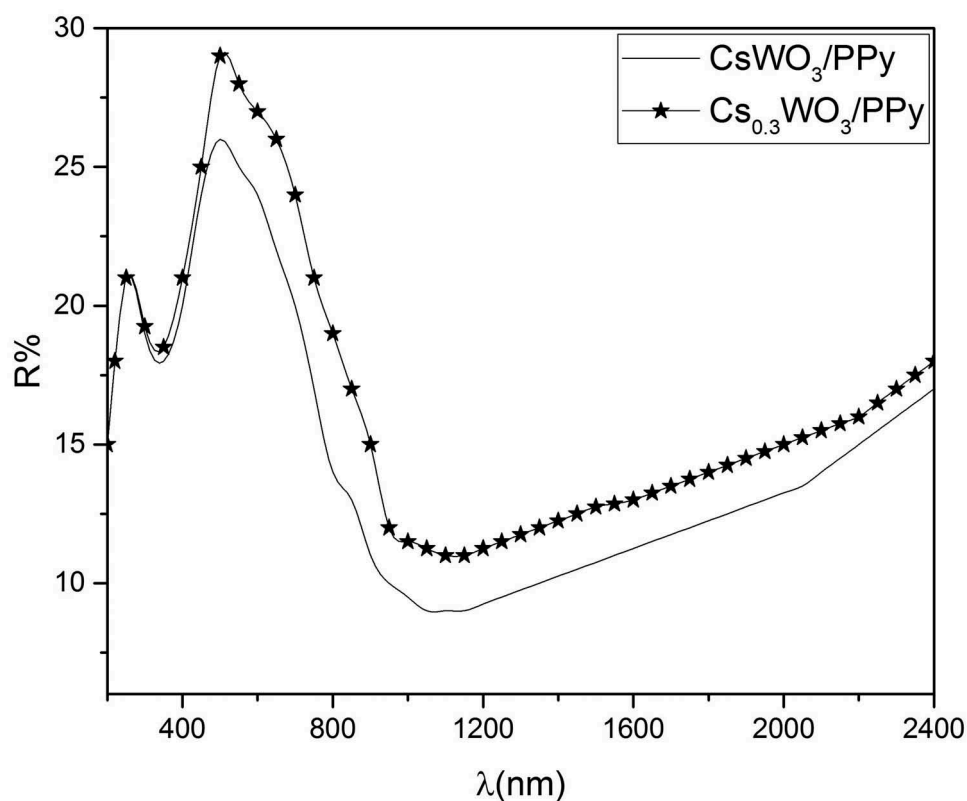

Figure 4. EDX image of  $Cs_xWO_3/PPy$ .

**Figure 5.** The UV-Vis-NIR reflection spectra of  $\text{CsWO}_3$  (a) and  $\text{Cs}_{0.3}\text{WO}_{2.7}$  (b) plates synthesised by solvothermal reaction under different thicknesses (0.5 mm, 0.75 mm and 1 mm).

**Figure 6.** The UV-Vis-NIR reflection spectra of  $\text{CsWO}_3/\text{PPy}$  and  $\text{Cs}_{0.3}\text{WO}_{2.7}/\text{PPy}$  nanocomposites prepared by interfacial polymerisation in 1 mm thickness.

$\text{WO}_{2.7}$  in higher thicknesses shifts towards the higher wavelength and low reflectance, which indicates different free carrier concentrations. In addition,  $\text{Cs}_{0.3}\text{WO}_{2.7}$  with more thicknesses exhibit higher NIR absorption (above 1400 nm) than the low thicknesses. Figure 6 shows the reflectance spectra of  $\text{Cs}_{0.3}\text{WO}_{2.7}/\text{PPy}$  nanocomposite with 1 mm thickness. Due to a lack of free electrons, the fully oxidised compound  $\text{Cs}_x\text{WO}_3$  showed no NIR shielding and after calcination at autoclave, all the  $\text{Cs}_x\text{WO}_3$  type products a certain degree of shielding performance of the visible and NIR were increased of PPy. The  $\text{Cs}_x\text{WO}_3/\text{PPy}$  showed the best performance as UV-Vis as well as excellent shielding properties in the NIR region.

## Conclusions

The caesium tungsten oxides were successfully synthesised by solvothermal and  $\text{Cs}_x\text{WO}_3/\text{PPy}$  nanocomposites with about 80 nm diameter were prepared by interfacial polymerisation of pyrrole. FESEM image shows the formation of spongy shape and EDX diagram shows the incorporation of  $\text{Cs}_x\text{WO}_3$  ( $x = 0.3$ ) into the polymer. The reflectance spectra result showed that the best UV-Vis-NIR shielding is  $\text{Cs}_{0.3}\text{WO}_{2.7}/\text{PPy}$  with 1 mm thickness. Such a nanocomposite not only could be used in the transparent solar heat-shielding filters, but also is useful for the development of UV-Vis-NIR shielding materials in medicine and military application.

## Disclosure statement

No potential conflict of interest was reported by the authors.

## Notes on contributors

**Seyed Hossein Hosseini** is full Professor of Organic Chemistry and Polymer Science at Imam Hossein and Islamic Azad Universities, Tehran-Iran. His was born in 10 September 1965. His main research interests cover conducting polymers (synthesis and applications) focus are design of new materials such as toxic gas sensors, conductive liquid crystalline polymers. The recent research activities include electromagnetic absorbing materials such as microwave, thermal IR, UV and laser, X-neutron-gama-ray, and etc. for industry and military applications. He has received numerous awards and he has more than 100 research publications in International journals. His main industrial researches are about cold cracking on extra heavy oil-bitumen, and industry resins.

**Ali Azimi** born 21 August 1991 in Tehran. The period Bachelor at field Applied Chemistry from Islamic Azad University, East Tehran Branch. A masters degree the field of polymer chemistry in Islamic Azad University, East Tehran Branch. currently a PhD student in Organic Chemistry at Islamic Azad University of Science and Technology in Tehran.

**M. Boujar Dolabi** was born 20 September 1983 in Tehran. My Bachelor science was at field applied chemistry from Islamic Azad University, Shareh Ray branch and master science degree at organic chemistry field in Payameh Noor University, Tehran. My research scopes are polymerization on electric and magnetic fields and preparation of IR absorbing materials.
